ATS integration exercise

> *The implementation of the exercise below is optional. You're welcome to experiment with it, but there is no expectation that you complete the implementation. We only ask that you read the brief and think through your approach. No code submission or working demo is expected; just be ready to discuss your approach.*

Build a small Node.js/TypeScript command-line tool that keeps a local job list up to date from our Greenhouse sandbox. Running it again should pick up new and changed jobs without creating duplicates.

Spend no more than 2 hours on the build. Stop after 2 hours and note any shortcuts or unfinished work. You may use AI tools, including Codex or Claude.

What to build

- Store only the Greenhouse job ID, title, raw description and status, such as open or closed.
- Use a JSON file or SQLite for local storage. No PostgreSQL setup is required.

Sandbox and API

Use Greenhouse Harvest API V3. Look into the jobs and job postings endpoints. We will share the sandbox credentials with you.

API documentation: https://harvestdocs.greenhouse.io

How to update the saved jobs

- Use the Greenhouse job ID to match source jobs to saved records.
- Add jobs with new IDs and update existing records when their data changes.

If fetching fails

Report the problem without wiping out previously saved data.

What to print after each run

Print a short summary of what changed.

What to submit

- A Node.js/TypeScript app that runs with one command.
- A shared GitHub link so we can review the code.

What we will check in the demo

Prepare a short presentation of your work. During the demo:

1. Import the sandbox jobs.
2. We will make live changes in the ATS.
3. Run the import again and show how your code handles those changes.

Not required

Do not build a UI, deployment setup, scheduler, bidirectional sync, job-deletion handling or an elaborate retry system.
